

## 1. Factorial Of A Number.

### Problem definition:

Find out the factorial of a given number

### Algorithm:

Algorithm Factorial(N)

IF N = 0 THEN:

Return 1

Else

Return Factorial(N-1)\*N

End If

### ▪ Prolog Code :

factorial(0, 1).

factorial(N, Result) :-

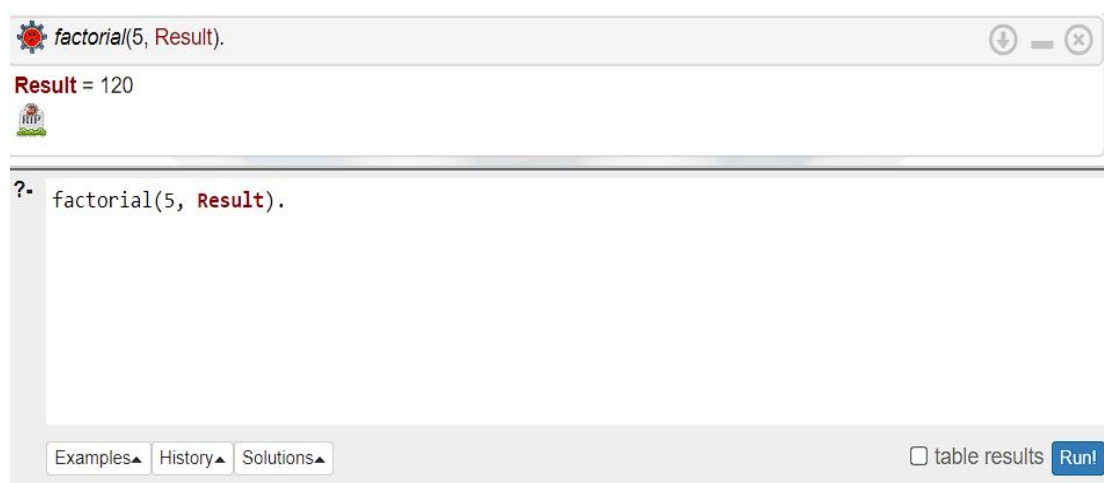

N > 0,

N1 is N - 1,

factorial(N1, SubResult),

Result is N \* SubResult

### ▪ Output:

The screenshot shows a Prolog interpreter window with the title bar "factorial(5, Result)." and standard window controls. The main area displays the result "Result = 120" in red text. Below this, there is a query prompt "?- factorial(5, Result)." in a text input field. At the bottom of the window, there are buttons for "Examples", "History", and "Solutions", along with a checkbox for "table results" and a blue "Run!" button.

## 2. GCD of two numbers.

- **Problem definition:**

Find out the Greatest Common Divisor of two numbers

- **Algorithm:**

Input: Two integers A and B

Output: An integer which is the GCD of A and B

Function gcd(a, b)

if a = 0

return b

end if

while b ≠ 0

if a > b

a ← a - b

else

b ← b - a

end if

End while

return a

- **Prolog Code :**

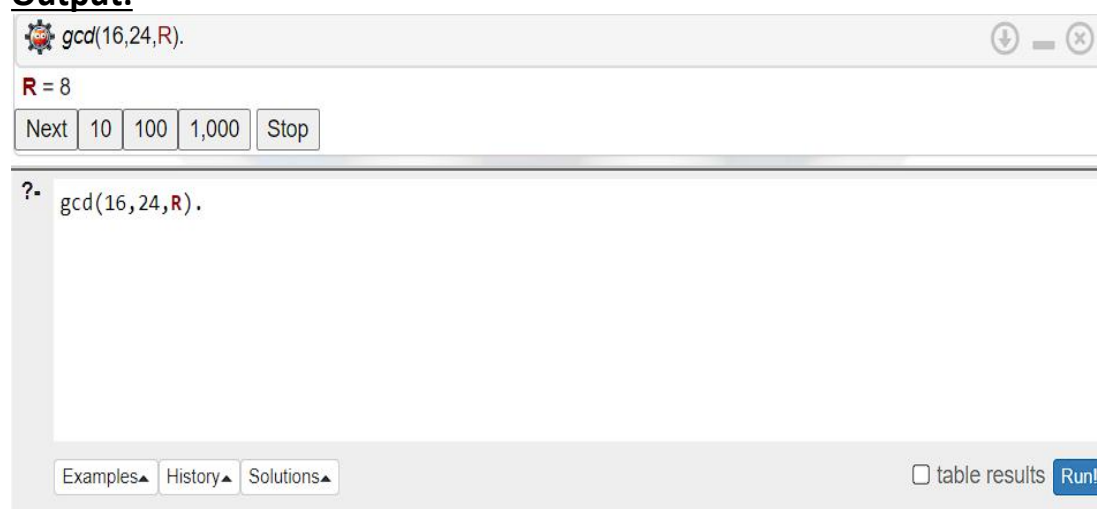

gcd(X,0,X).

gcd(X,Y,Z):-

R is mod(X,Y),

gcd(Y,R,Z).

- **Output:**

The screenshot shows a Prolog interpreter window with the title bar "gcd(16,24,R)." and standard window controls. The main area displays the result "R = 8". Below this, there are buttons for "Next", "10", "100", "1,000", and "Stop". At the bottom, there are tabs for "Examples", "History", and "Solutions", along with a checkbox for "table results" and a "Run!" button.

### 3.Prime Number.

- **Problem Definition:**

Find Out Either e given number prime or not.

- **Algorithm:**

```
function isPrime(N):
```

```
  if N <= 1:
```

```
    return false
```

```
  for i from 2 to square root of N:
```

```
    if N is divisible by i:
```

```
      return false
```

```
  return true
```

- **Prolog Code:**

```
% Base case: 0 and 1 are not prime
```

```
is_prime(0) :- false.
```

```
is_prime(1) :- false.
```

```
% Predicate to check if N is divisible by any number up to the square root of N
```

```
is_divisible(N, Div) :-
```

```
  N > 1,
```

```
  N1 is N - 1,
```

```
  between(2, N1, Div),
```

```
  0 is N mod Div.
```

```
% A number is prime if it's not divisible by any number other than 1 and itself
```

```
is_prime(N) :-
```

```
  N > 1,
```

```
  not(is_divisible(N, _)).
```

- **Output:**

The screenshot shows a Prolog interpreter window titled 'is\_prime(7)'. The main text area displays a red error message: 'Clauses of is\_prime/1 are not together in the source-file'. Below this, it says 'Earlier definition at line 2' and 'Current predicate: is\_divisible/2'. A suggestion is given: 'Use :- discontinuous is\_prime/1. to suppress this message'. Below the error message, the text 'true' is displayed. At the bottom of the window, there is a query prompt '?-' followed by 'is\_prime(7)'. The bottom status bar includes buttons for 'Examples', 'History', and 'Solutions', along with a checkbox for 'table results' and a 'Run!' button.

#### 4. Fibonacci series.

- **Problem definition:**

Find out the Fibonacci series

- **Algorithm:**

Input: integer N such that  $N > 0$

Output: A sequence of integer numbers

Function Fib is

IF  $N=0$  THEN:

return 0

ELSE if  $N=1$

return 1

ELSE

return  $\text{Fib}(N-1) + \text{Fib}(N-2)$

END IF

END Fib

- **Prolog Code :**

`fib_seq(0,[0]).`                      % <- base case 1

`fib_seq(1,[0,1]).`                    % <- base case 2

`fib_seq(N,Seq) :-`

$N > 1$ ,

`fib_seq_(N,SeqR,1,[1,0]),`      % <- actual relation (all other cases)

`reverse(SeqR,Seq).`              % <- reverse/2 from library(lists)

`fib_seq_(N,Seq,N,Seq).`

`fib_seq_(N,Seq,N0,[B,A|Fs]) :-`

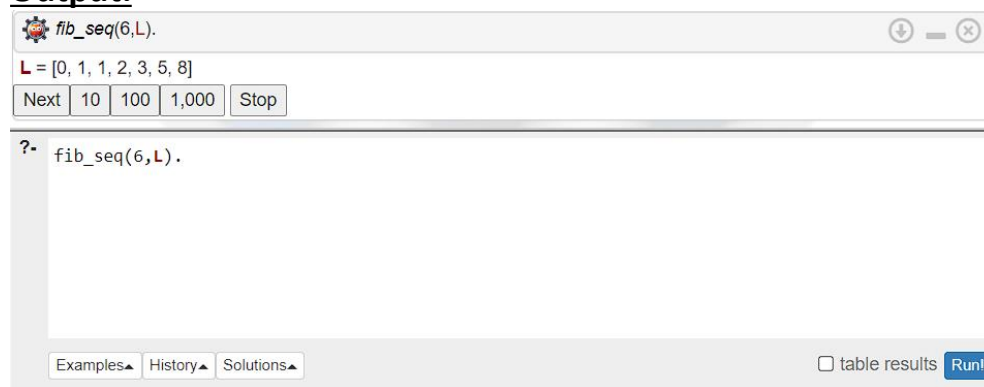

$N > N0$ ,

$N1$  is  $N0+1$ ,

    C is  $A+B$ ,

`fib_seq_(N,Seq,N1,[C,B,A|Fs]).` % <- tail recursion

- **Output:**

## 5. Family Tree Problem.

### ▪ Problem Definattion:

Execute Family Tree in Class.

### ▪ Algorithm:

Facts:

```
parent(john, mary).
parent(john, adam).
parent(eve, mary).
parent(eve, adam).
parent(mary, julie).
parent(adam, peter).
```

Rules:

```
father(Father, Child) :-
    parent(Father, Child),
    male(Father).
```

```
mother(Mother, Child) :-
    parent(Mother, Child),
    female(Mother).
```

```
sibling(Person1, Person2) :-
    parent(Parent, Person1),
    parent(Parent, Person2),
    Person1 \= Person2.
```

```
brother(Brother, Person) :-
    sibling(Brother, Person),
    male(Brother).
```

```
sister(Sister, Person) :-
    sibling(Sister, Person),
    female(Sister).
```

```
grandparent(Grandparent, Grandchild) :-
    parent(Grandparent, Parent),
    parent(Parent, Grandchild).
```

Predicates for Genders:

```
male(john).
male(adam).
male(peter).
```

```
female(eve).
female(mary).
female(julie).
```

### ▪ **Prolog Code:**

% Facts defining the relationships in the family tree

parent(john, mary).

parent(john, adam).

parent(eve, mary).

parent(eve, adam).

parent(mary, julie).

parent(adam, peter).

% Rules for defining various relationships

father(Father, Child) :-

parent(Father, Child),

male(Father).

mother(Mother, Child) :-

parent(Mother, Child),

female(Mother).

sibling(Person1, Person2) :-

parent(Parent, Person1),

parent(Parent, Person2),

Person1 \= Person2. % Ensuring they are not the same person

brother(Brother, Person) :-

sibling(Brother, Person),

male(Brother).

sister(Sister, Person) :-

sibling(Sister, Person),

female(Sister).

grandparent(Grandparent, Grandchild) :-

parent(Grandparent, Parent),

parent(Parent, Grandchild).

% Predicates for genders (can be extended with more details)

male(john).

male(adam).

male(peter).

female(eve).

female(mary).

female(julie).

### ▪ **Output:**

```

father(john, mary).
true

brother(X, mary).
X = adam

?- brother(X, mary).

```

## 6. Towers Of Hanoi.

### ▪ **Problem definition:**

Find out the solution of the famous towers of Hanoi problem

### ▪ **Algorithm:**

FUNCTION MoveTower(disk, source, dest, spare):

    IF disk == 0, THEN:

        move disk from source to dest

    ELSE:

        MoveTower(disk - 1, source, spare, dest) // Step 1 above

        move disk from source to dest // Step 2 above

        MoveTower(disk - 1, spare, dest, source) // Step 3 above

    END IF

### ▪ **Prolog Code :**

% Define the predicate for Towers of Hanoi

hanoi(1, Start, End, \_, Moves) :-

    % Base case: When there's only one disk, move it from Start to End

    append(['Move disk from ', Start, ' to ', End], [], Moves).

hanoi(N, Start, End, Aux, Moves) :-

    % Recursive case: Move N-1 disks from Start to Aux using End as the auxiliary peg

    N > 1,

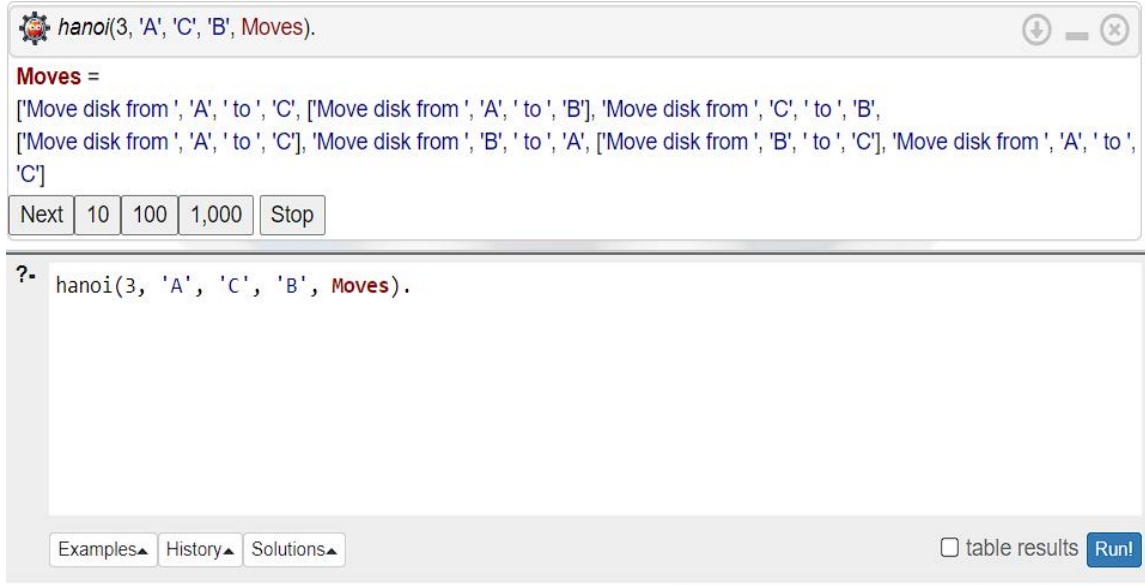

    N1 is N - 1,

```

hanoi(N1, Start, Aux, End, FirstMoves),
% Move the largest disk from Start to End
append(['Move disk from ', Start, ' to ', End], [], Move),
% Move the N-1 disks from Aux to End using Start as the auxiliary peg
hanoi(N1, Aux, End, Start, LastMoves),
% Concatenate the moves
append(FirstMoves, [Move | LastMoves], Moves).

```

▪ **Output:**

The screenshot shows a MATLAB Command Window with the following content:

hanoi(3, 'A', 'C', 'B', Moves).

**Moves =**

```

['Move disk from ', 'A', ' to ', 'C', ['Move disk from ', 'A', ' to ', 'B'], 'Move disk from ', 'C', ' to ', 'B',
['Move disk from ', 'A', ' to ', 'C'], 'Move disk from ', 'B', ' to ', 'A', ['Move disk from ', 'B', ' to ', 'C'], 'Move disk from ', 'A', ' to ',
'C']

```

Below the output, there are buttons for 'Next', '10', '100', '1,000', and 'Stop'.

At the bottom of the window, there is a prompt '?-' followed by the command `hanoi(3, 'A', 'C', 'B', Moves).` and a 'Run!' button.

## 7.Eight Queens.

- **Problem definition:**

Find out the solution of the famous 8 queen problem

- **Algorithm:**

```
//initialize row, then find
//first acceptable solution for self and
//neighbor
//advance advance row and find next
//acceptable solution
//canAttack-see whether a position can
//be attacked by self or neighbors
```

```

## 8. Water Jug Problem.

### Problem Definition:

You are given two empty jugs with capacities `Jug1Capacity` and `Jug2Capacity` in units of water. The goal is to measure a specific quantity of water `TargetQuantity` using these jugs. The following actions can be performed:

- Fill a jug completely.
- Empty a jug completely.
- Pour water from one jug into another until the pouring jug is empty or the receiving jug is full.

The problem is to determine whether it's possible to measure the `TargetQuantity` of water using the given jugs and, if possible, provide the sequence of actions to achieve this goal.

### ▪ Algorithm:

```
function WaterJugProblem(Jug1Capacity, Jug2Capacity, TargetQuantity):
```

```
  initialize a stack to store states (initially empty)
```

```
  initialize a set to store visited states (initially empty)
```

```
  push initial state (0, 0) to the stack (representing both jugs empty)
```

```
  while the stack is not empty:
```

```
    current_state = pop state from the stack
```

```
    if current_state matches the TargetQuantity:
```

```
      return sequence of actions to achieve the TargetQuantity
```

```
  if current_state is not in visited states:
```

```
    mark current_state as visited
```

```
  for each possible action in Fill Jug 1, Fill Jug 2, Empty Jug 1, Empty Jug 2,
```

```
  Pour Jug 1 to Jug 2, Pour Jug 2 to Jug 1:
```

```
    new_state = apply action to current_state (simulate the action)
```

```
    if new_state is valid and not visited:
```

```
      push new_state to the stack
```

```
  return "TargetQuantity cannot be achieved with the given jugs"
```

```
function apply action to current_state:
```

```
  simulate the action on current_state to generate a new_state
```

```
  return new_state if the action is feasible (within jug capacities and non-negative values)
```

```
  otherwise, return an invalid state
```

▪ **Prolog Code:**

## 9. Missionaries and Cannibals problem.

- **Problem Definition:**

- There are three missionaries and three cannibals on one side of the river.
- A boat is available that can carry at most two individuals at a time.
- The goal is to move all the missionaries and cannibals to the other side of the river without violating the following constraints:
- At any point, the number of cannibals on either side of the river cannot exceed the number of missionaries, otherwise, the cannibals would overpower and eat the missionaries.
- The boat must always have at least one person (missionary or cannibal) to operate it.

- **Algorithm:**

function solveMissionariesAndCannibals():

  initialize an empty stack to store states

  push initial state (3, 3, 0) to the stack

  initialize an empty set to store visited states

  add initial state (3, 3, 0) to the visited set

  while stack is not empty:

    current\_state = pop state from stack

    if current\_state is the goal state (0, 0, 1):

      return sequence of actions to reach the goal state

  for each possible action in MoveOne, MoveTwo, MoveOneBack, MoveTwoBack:

    new\_state = apply action to current\_state

    if new\_state is valid and not in visited states:

      push new\_state to stack

      add new\_state to visited states

  return "No solution found"

function apply action to current\_state:

  simulate the action on current\_state to generate a new\_state

  return new\_state if the action is feasible (adheres to constraints)

  otherwise, return an invalid state

▪ **Prolog Code:**

% Find the solution for the missionaries and cannibals problem
find :-
path([3,3,left,0,0],[0,0,right,3,3],[[3,3,left,0,0]],_).
```

### ▪ Output:

The screenshot shows a MATLAB script execution window titled 'find.'. The output displays a sequence of states and moves for the missionaries and cannibals problem. The states are represented as [M1, M2, left, C1, C2], where M1 and M2 are missionaries on the left bank, left is the boat position, and C1 and C2 are cannibals on the left bank. The moves are indicated by arrows. The sequence ends with 'true'. Below the output are buttons for 'Next', '10', '100', '1,000', and 'Stop'. The bottom panel shows the command prompt with '?- find.' and a 'Run!' button.

```
[3, 3, left, 0, 0] -> [1, 3, right, 2, 0]
[1, 3, right, 2, 0] -> [2, 3, left, 1, 0]
[2, 3, left, 1, 0] -> [0, 3, right, 3, 0]
[0, 3, right, 3, 0] -> [1, 3, left, 2, 0]
[1, 3, left, 2, 0] -> [1, 1, right, 2, 2]
[1, 1, right, 2, 2] -> [2, 2, left, 1, 1]
[2, 2, left, 1, 1] -> [2, 0, right, 1, 3]
[2, 0, right, 1, 3] -> [3, 0, left, 0, 3]
[3, 0, left, 0, 3] -> [1, 0, right, 2, 3]
[1, 0, right, 2, 3] -> [1, 1, left, 2, 2]
[1, 1, left, 2, 2] -> [0, 0, right, 3, 3]
true
```

## 10. Breadth First Search.

- **Problem Definition:**

Given a tree or graph, perform a Breadth-First Search to traverse the structure and visit all nodes in a breadthward motion.

- **Algorithm:**

```
function BFS(graph, startNode):
  create an empty queue
  create an empty set to keep track of visited nodes

  enqueue startNode into the queue
  add startNode to the set of visited nodes

  while the queue is not empty:
    currentNode = dequeue from the queue
    process currentNode (visit or perform required operation)

  for each neighbor of currentNode:
    if neighbor is not visited:
      enqueue neighbor into the queue
      add neighbor to the set of visited nodes
```

- **Prolog Code:**

```
% solve( Start, Solution):
%   Solution is a path (in reverse order) from Start to a goal

solve( Start, Solution) :-
  breadthfirst( [ [Start] ], Solution).

% breadthfirst( [ Path1, Path2, ...], Solution):
%   Solution is an extension to a goal of one of paths

breadthfirst( [ [Node | Path] | _], [Node | Path]) :-
  goal( Node).

breadthfirst( [Path | Paths], Solution) :-
  extend( Path, NewPaths),
  append( Paths, NewPaths, Paths1),
  breadthfirst( Paths1, Solution).

extend( [Node | Path], NewPaths) :-
```

```

bagof( [NewNode, Node | Path],
( s( Node, NewNode), \+ member( NewNode, [Node | Path] ) ),
NewPaths),
!.

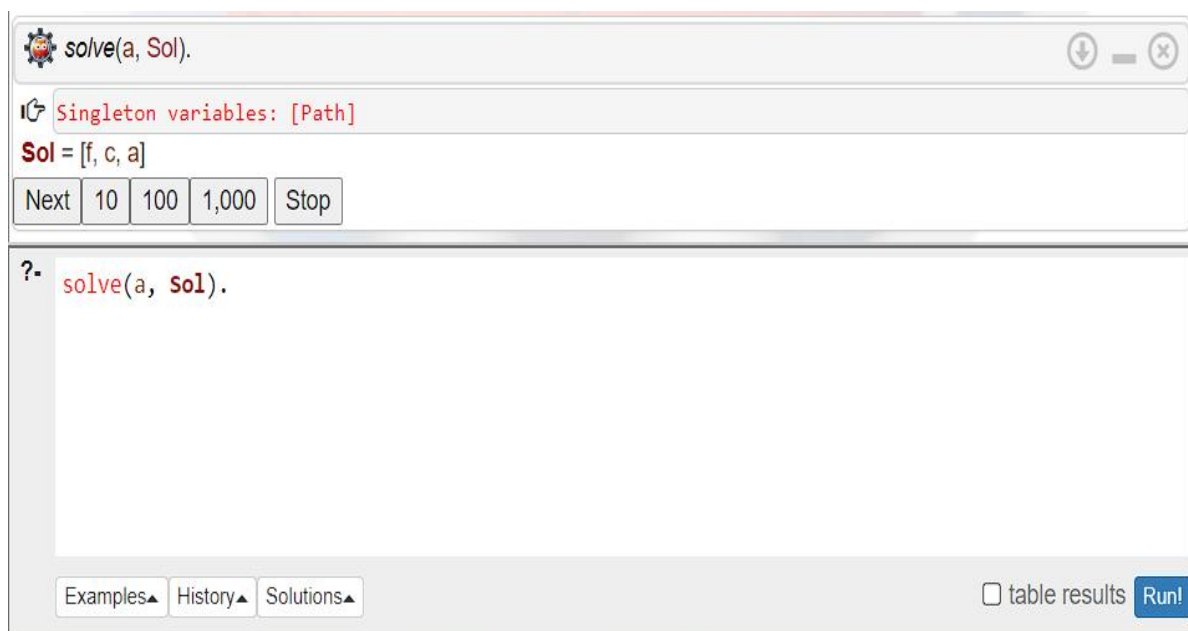

```

```

extend( Path, [] ).      % bagof failed: Node has no successor
s(a,b).
s(a,c).
s(b,d).
s(b,e).
s(c,f).
s(c,g).
s(d,h).
s(e,i).
s(e,j).
goal(j).
goal(f).

```

▪ **Output:**

## 11.Depth First Search.

- **Problem Definition:**

Given a tree or graph, perform a Depth-First Search to traverse the structure and visit all nodes in a depthward motion.

- **Algorithm:**

```
function DFS(Graph, StartNode):
create an empty stack to store nodes to be explored
create an empty set to keep track of visited nodes

push StartNode onto the stack
add StartNode to the set of visited nodes

while the stack is not empty:
currentNode = pop from the stack
process currentNode (visit or perform required operation)

for each neighbor of currentNode:
if neighbor is not visited:
push neighbor onto the stack
add neighbor to the set of visited nodes
```

- **Code:**

```
% solve( Node, Solution):
%   Solution is an acyclic path (in reverse order) between Node and a goal

solve( Node, Solution) :-
depthfirst( [], Node, Solution).

% depthfirst( Path, Node, Solution):
%   extending the path [Node | Path] to a goal gives Solution

depthfirst( Path, Node, [Node | Path] ) :-
goal( Node).

depthfirst( Path, Node, Sol) :-
s( Node, Node1),
\+ member( Node1, Path),          % Prevent a cycle
depthfirst( [Node | Path], Node1, Sol).

depthfirst2( Node, [Node], _ ) :-
goal( Node).
```

```

depthfirst2( Node, [Node | Sol], Maxdepth) :-
  Maxdepth > 0,
  s( Node, Node1),
  Max1 is Maxdepth - 1,
  depthfirst2( Node1, Sol, Max1).

```

```

goal(f).
goal(j).
s(a,b).
s(a,c).
s(b,d).
s(b,e).
s(c,f).
s(c,g).
s(d,h).
s(e,i).
s(e,j).

```

▪ **Output:**

The screenshot shows a Prolog IDE window titled "solve(a, Sol)". The main display area shows the solution **Sol = [j, e, b, a]**. Below this is a control bar with buttons for "Next", "10", "100", "1,000", and "Stop". The bottom section of the window contains a query prompt "?- solve(a, Sol)." and a footer bar with "Examples", "History", "Solutions", "table results", and a "Run!" button.
